Valve Operation

In Figure 1, the upper adjusting ring (G) is positioned to attain full lift at pop and to control the pressure at which the valve will begin to close. The lower adjusting ring (O) ensures a sharp pop action at the set pressure and cushions the valve on closing.

When full lift is attained (Figure 2), the lift stop (M) rests against the yoke (T) to eliminate rapid opening and closing of the valve, adding stability to the valve. When the valve discharges in an open position, steam is bled into the chamber (H) through two bleed holes (J) in the roof of the disc holder. The steam escapes to the atmosphere through the pipe discharge connection (R). Figure 1: Closed

Features and Benefits

Lifting Gear

Adjustable position for flexibility and ease of installation.

Advanced Yoke Design

Provides spring cooling and ensures stable set pressure.

Thrust Bearing

Promotes accurate and simple adjustment of set pressures when in service and also promotes uniform loading of the valve spring.

Stainless Steel Spindle

Has spherical bearing with large contact area for low unit loading. Low spindle point improves seat tightness.

Precision Wound Spring

Specifically designed to eliminate eccentric loading and to provide full relieving capacity at minimum accumulation.

Vented Cover Plate

Allows the valve to attain full lift at 3 percent overpressure.

Adjustable Lift Stop

Matches safety valve capacity to boiler capacity, eliminates overpressure, protects against chatter, reduces reaction forces, assists stack sizing and protects against over-compression of the spring.

Grooved Disc Holder

Prevents disc rotation and permits motion with minimum friction.

Upper Adjusting Ring

Attains full lift at pop and controls the pressure at which the valve will begin to close.

High Capacity Discharge

Provides higher rated capacity and increases allowable backpressure to 25 percent of the valve's set pressure.

Thermodisc™

Designed to eliminate distortion due to thermal stresses. Temperature differentials quickly equalize for permanent tightness.

Lower Adjusting Ring

Promotes sharp pop action of the valve on opening and cushions the valve on closing.

Inlet Connection

Welded or flange.

Thermodisc Design

The Thermodisc seat was designed and developed to address the problem of safety valve leakage. The disc design uses Inconel material and has an improved spindle pocket with concentric loading of the disc. These features, when combined with a low spindle bearing point and a thin flexible seat can provide a superior safety valve that has repeatable seat tightness.

Inconel Disc Material

Inconel material can provide superior corrosive resistance and strength at high temperatures over a long period of time. The strength of the Inconel material prevents distortion in the spindle/disc contact area during actuation. A more durable disc material helps to maintain the safety valves original set pressure despite numerous actuations and further improves the longevity of the safety valve.

Concentric Disc Loading

Concentric disc loading equalizes the spring force being transmitted to the valve seating area. The disc remains concentric to the center line of the valve nozzle so that the valve will reseat in its original seating position. The effective seating area remains constant, producing repeatable valve opening pressures.

Low Spindle Bearing Point

A low spindle bearing point locates the point of spring force transmission below the horizontal seat line of the valve, which minimizes the natural tendency for the disc to assume a horizontally tilted position during the opening and closing cycle of the valve. The low spindle bearing point further promotes equalized spring force distribution at the valve seat and helps to maintain seat tightness.

Thin Flexible Design

The thin seat design compensates for temperature changes by equalizing the temperature in the disc, thereby reducing distortions. Flexibility also allows the system pressure to assist the mechanical loading and produce a line contact at the sealing surface of the seat bushing; the critical seating area remains constant for consistent, repeatable valve opening.
